1 Introduction

Cefas and JNCC undertook a survey of the North East of Farnes Deep (NEFD) and Farnes East (FRNE) Marine Conservation Zones (MCZ) between 23 April and 4 May 2018. The following report details the activities undertaken on the survey. Samples were collected at both sites which will be analysed in line with the survey objectives. The results of these analyses will be presented in a separate report and published on the JNCC website.

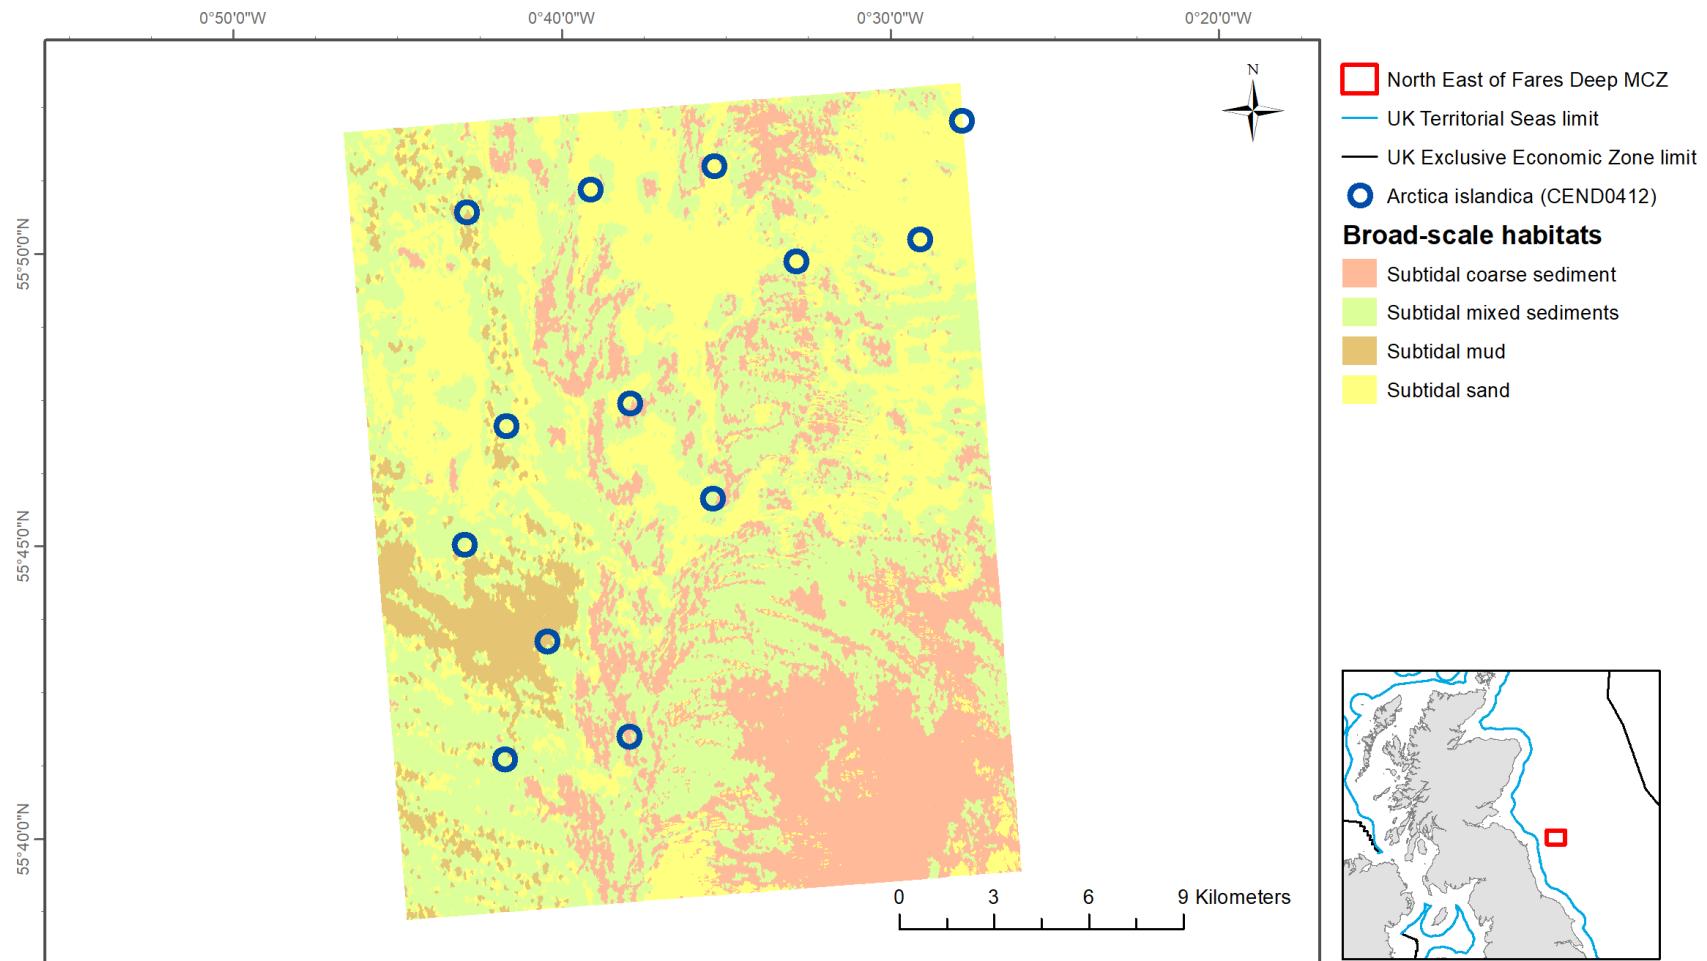

1.1 Site descriptions

1.1.1 North East of Farnes Deep MCZ

North East of Farnes Deep MCZ is located approximately 55km offshore from the north Northumberland coast, in the northern North Sea. The site has a total area of 492km² and a depth range between 50 to 100m below chart datum; the deepest section of the site runs parallel to the western boundary and the shallowest section is in the south-east quarter. Subtidal mixed sediments occupy almost half of the MCZ; subtidal sand and subtidal coarse sediment each occupy approximately a quarter of the total site area, with a small area of subtidal mud present in the west of the site. All the subtidal sediment types found within North East of Farnes Deep MCZ are designated as features of the site. The most up to date BSH map for the site at the time of survey was produced from data collected during the joint JNCC/Cefas survey in 2012 (survey code: CEND0412) (Eggleton *et al.* 2015)(Figure 1). The long-lived Ocean quahog (*Arctica islandica*) Feature of Conservation Importance (FOCI), is also recorded at the site and listed as a designated feature (Table 1, Figure 1). The Ocean quahog is an OSPAR Threatened and/or Declining species (OSPAR 2018) and a species Feature of Conservation Importance (FOCI) listed on the Ecological Network Guidance (JNCC & Natural England 2010).

Although not designated features of the site, geological/geomorphological features are also present in the form of depositional glacial features and topographic features of the North-East Bank seabed mound or pinnacle.

Table 1. Designated features of North East of Farnes Deep MCZ and General Management Approaches (GMA).

Designated Features	General Management Approach (GMA)
Subtidal coarse sediment (A5.1)	Maintain in favourable condition.
Subtidal sand (A5.2)	Maintain in favourable condition.
Subtidal mud (A5.3)	Maintain in favourable condition.
Subtidal mixed sediments (A5.4)	Maintain in favourable condition.
Ocean quahog	Maintain in favourable condition.

1.1.2 Farnes East MCZ

Farnes East MCZ is a joint inshore and offshore site situated off the north east of England, approximately 11km from the Northumberland coast. A section of the eastern boundary of the site follows the 6nm line. The site has a total area of 945km² and ranges in depth from 30m to 100m. The seabed is predominantly composed of subtidal sediments with a scattering of small patches of moderate energy circalittoral rock. The shallower areas of the site, in the west, are dominated by subtidal coarse sediment and subtidal mixed sediments, while the eastern side is largely subtidal sand. A section of the Farnes Deep glacial trench occurs within the site boundary. The trench, which is the deepest part of the MCZ, contains subtidal mud. The most up to date BSH map for the site at the time of survey was produced from data collected during the joint JNCC/Cefas survey in 2012 (survey code: CEND0412) (Murray *et al.* 2015), (Figure 2). All the subtidal sediment types and the circalittoral rock found within Farnes East MCZ are listed as protected features (Table 2). The sedimentary habitats in Farnes East MCZ also support Ocean quahog (*Arctica islandica*), which is a designated feature of the site (Figure 2, Table 2). Two species of sea pen; slender sea pen (*Virgularia mirabilis*) and phosphorescent sea pen (*Pennatula phosphorea*) have been observed living in the mud habitat. Norway lobster (*Nephrops norvegicus*) construct burrows within the deep mud habitat. As a result, the habitat FOCI 'Sea pen and burrowing megafauna communities' is also protected in Farnes East MCZ (Figure 2, Table 2).

For further information on this site please refer to JNCC's Site Information Centre (<http://jncc.defra.gov.uk/page-6773>).

Figure 2. Map showing location of Farnes East MCZ and the distribution of Broad-Scale Habitats within the MCZ boundary. BSH data source Murray et al. (2015). *Arctica Islandica* records are from CEND0412 and Sea pen and burrowing megafauna records are from CEND0514.

Table 2. Designated features of Farnes East MCZ and General Management Approaches (GMA).

Designated Feature/s	General Management Approach (GMA)
Moderate energy circalittoral rock (A4.2)	Maintain in favourable condition.
Subtidal coarse sediment (A5.1)	Maintain in favourable condition.
Subtidal sand (A5.2)	Maintain in favourable condition.
Subtidal mud (A5.3)	Recover to favourable condition.
Subtidal mixed sediments (A5.4)	Maintain in favourable condition.
Sea pen and burrowing megafauna communities	Recover to favourable condition.
Ocean quahog	Recover to favourable condition.

2 Survey Aims and Objectives

2.1 North East of Farnes Deep MCZ

At North East of Farnes Deep (NEFD) MCZ, the aim of the survey was to investigate the potential impact of restricting bottom trawling as part of the management measures for the site, using an operational (Type 2) monitoring approach. The area of interest for the survey is in the south-eastern corner of the site, which overlaps the tail-end of a sand-eel fishery. The prioritised primary objectives of the survey are detailed in Table 3, along with an indication of whether the objective was completed or not during the survey.

Table 3. Monitoring objectives for the CEND0618 North East of Farnes Deep MCZ survey.

2.2 Farnes East MCZ

At Farnes East (FRNE) MCZ, the aim of the survey was to acquire sentinel monitoring (Type 1 monitoring) data to contribute to the development of a monitoring time-series for the Farnes East MCZ. This site was visited previously in 2012 (Cefas survey CEND0412) and 2014 (Cefas survey CEND0514) but as the aim of these surveys focussed on site verification, CEND0618 will form the first time point of a dedicated monitoring dataset. However, this will not preclude their *ad hoc* comparison with existing data from the sites.

The survey gathered evidence on the extent, distribution, structure and functions, and supporting processes relating to the designated features of the site (Table 2) against which the rate and direction of change can be inferred in the long-term. The primary objectives of the survey are presented in Table 4. Several lower priority objectives were included as contingency. They were to be completed if more time was available or if there were problems with a piece of equipment. It was not expected that all objectives would be completed during CEND0618.

It is noted that data from this survey will form part of a monitoring time series and that future repeated monitoring and evidence gathering will be required to fully investigate and understand the temporal variability in the parameters measured.

Table 4. Monitoring objectives for the CEND0618 Farnes East MCZ survey.

Objective (attributes in bold)	Sub-objectives	Priority	Rationale/Justification	Hypotheses
1. Collect evidence to inform Type 1 (sentinel) monitoring of the biological and physical ; • extent and distribution , and, • structure and functions , and, • quality and composition of the subtidal mud feature of FRNE and, where available, the quality and quantity of the habitat supporting the FOCI Sea pen and burrowing megafauna communities and, if available, the composition of the FOCI.	<p>1.1 Acquire quantitative infaunal data using a mini-Hamon grab (integrated with sub-objective 1.3).</p> <p>1.2. There is no difference/change in measured infaunal communities associated with the subtidal mud feature within the site from T0 and T1.
		1	Acquire quantitative and semi-quantitative epifaunal community data to enable sentinel (Type 1) monitoring of the subtidal mud feature and the FOCI feature, Sea pen and burrowing megafauna communities, within the site.	There is no difference/change in measured subtidal mud epifaunal communities within the site from T0 and T1 and there is no difference/change in supporting habitats for the FOCI (Sea pen and burrowing megafauna communities) within and outside the site at T0 and T1.
		1	Acquire quantitative data to enable sentinel (Type 1) monitoring of the physical attributes of the sediment supporting the infaunal communities associated with the subtidal mud feature within the site.	There is no difference/change in the physical attributes of the sediment supporting the infaunal communities associated with subtidal mud feature within the site at T0 and T1.
2. Collect evidence to inform Type 1 (sentinel) monitoring of the biological and physical ; • extent and distribution , and, • structure and functions , and, • quality and composition associated with the subtidal coarse sediment , subtidal sand , and subtidal mixed sediments features of FRNE.	<p>2.1 Acquire quantitative infaunal data using mini-Hamon grab samples (integrated with sub-objective 2.3).</p> <p>2.2. Acquire semi-quantitative epifaunal data using drop frame camera to capture video and stills imagery (integrated with sub-objective 2.4).</p>	2	Acquire quantitative data to enable sentinel (Type 1) monitoring of the subtidal coarse sediment , Subtidal sand , and Subtidal mixed sediments features within the site.	There is no difference/change in measured infaunal communities associated with subtidal coarse sediment , subtidal sand , and subtidal mixed sediments features, respectively, within the site at sentinel stations from T0 and T1.
		3	Acquire semi-quantitative data to enable sentinel (Type 1) monitoring of the subtidal coarse sediment , and subtidal mixed sediments feature within the site.	There is no difference/change in measured subtidal coarse sediment , and subtidal mixed sediments epifaunal community features, respectively, within the site at sentinel stations from T0 and T1.

	2.3. Acquire sediment samples using mini-Hamon grab (integrated into sub-objective 2.1).	2	Acquire quantitative data to enable sentinel (Type 1) monitoring of the physical attributes of the sediment supporting the infaunal communities associated with the subtidal coarse sediment , subtidal sand , and subtidal mixed sediments features within the site.	There is no difference/change in the physical attributes of the sediment supporting the infaunal communities associated with the subtidal coarse sediment , subtidal sand , and subtidal mixed sediments features, respectively, within the site at T0 and T1.
	2.4. Acquire semi-quantitative data using drop frame camera to capture video and stills imagery (integrated with sub-objective 2.2).	3	Acquire semi-quantitative data to enable sentinel (Type 1) monitoring of the extent, distribution and physical structure of subtidal coarse sediment and subtidal mixed sediments features within the site.	There is no difference/change in measured subtidal coarse sediment , and subtidal mixed sediments BSH features, respectively, within the site at T0 and T1.
3. Collect evidence to inform Type 1 (sentinel) monitoring of the biological and physical ; <ul style="list-style-type: none">• extent and distribution; and,• structure and functions, and,• quality and composition associated with the moderate energy circalittoral rock features of FRNE.	3.1. Acquire semi-quantitative epifaunal community data using drop frame camera to capture video and stills imagery (integrated with sub-objective 3.2).	3	Acquire semi-quantitative data to enable sentinel (Type 1) monitoring of the epifaunal community associated with the moderate energy circalittoral rock feature within the site.	There is no difference/change in measured moderate energy circalittoral rock epifaunal community features, respectively, within the site at sentinel stations from T0 and T1.
	3.2. Acquire semi-quantitative data using drop frame camera to capture video and stills imagery (integrated with sub-objective 3.1).	3	Acquire semi-quantitative data to enable sentinel (Type 1) monitoring of the extent, distribution and physical structure of the moderate energy circalittoral rock feature within the site.	There is no difference/change in the physical attributes of the moderate energy circalittoral rock feature, respectively, within the site at T0 and T1.
4. Collect evidence to inform Type 1 (sentinel) monitoring of the supporting processes relating to subtidal mud , subtidal coarse sediment , subtidal sand , subtidal mixed sediment and moderate energy circalittoral rock features of FRNE, respectively, by priority.	4.1. Acquire CTD and ESM Logger data transmissometer data (integrated with sub-objectives 1.2, 2.2, 2.4, 3.1 and 3.2, as applicable).	4	Acquire quantitative environmental data (e.g., temperature, salinity and turbidity) to improve understanding of environmental conditions and natural supporting processes at the seabed within to the site.	<ul style="list-style-type: none"> • Hypothesis not required. • Supporting processes will not be compared within the site, at sentinel stations, from T0 and T1, but will provide context of environmental variability.

	4.2. Acquire Ferrybox data continuously during survey.	4		
5. Collect evidence to inform Type 1 (sentinel) monitoring of the quality and quantity of habitat supporting species FOCI , Ocean quahog , and, if available, the composition of the FOCI.	5.1 Acquire semi-quantitative epifaunal data using video and stills imagery within areas of interest within FRNE (integrated with sub-objectives 1.2, 2.2, 2.4, 3.1 and 3.2, as applicable). 5.2 Acquire quantitative epifaunal data using grab sampling, using a mini-Hamon grab, within areas of interest in FRNE (integrated with sub-objectives 1.1, 1.3, 2.1, 2.3).	3 2	Acquire quantitative and semi-quantitative data to enable sentinel (Type 1) monitoring of the habitat supporting the species FOCI, Ocean quahog, within the site.	There is no difference/change in supporting habitat for Ocean quahog populations within and outside the site at T0 and T1 .

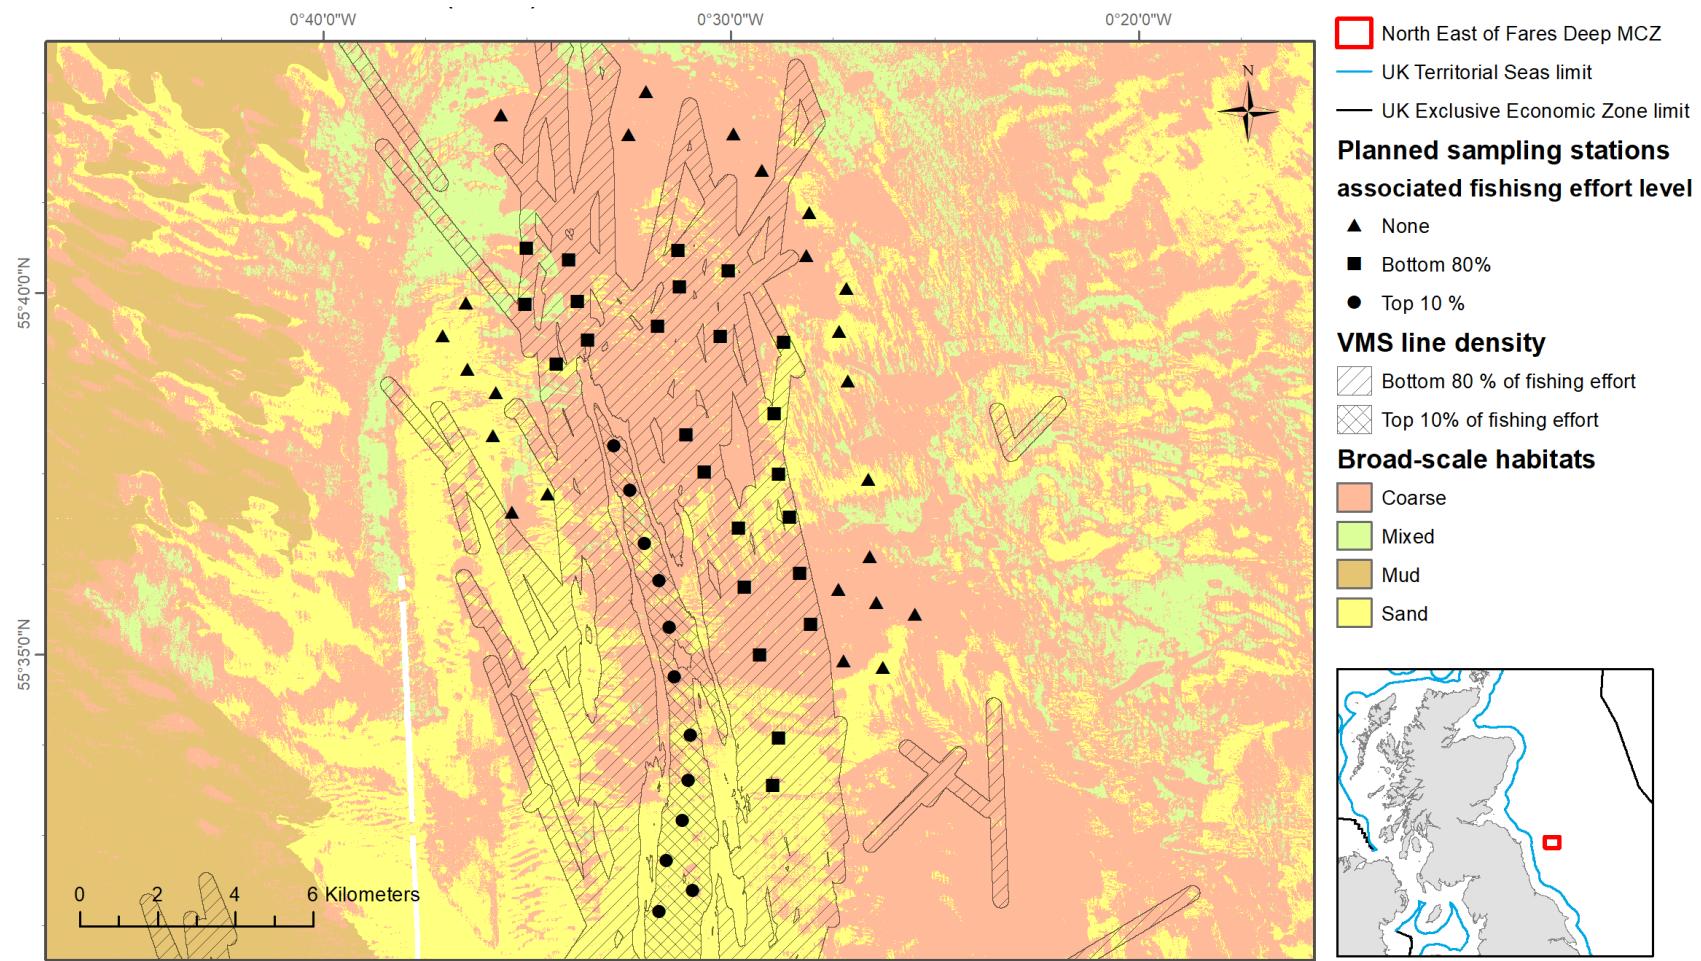

3 Survey Planning and Design

3.1 North East of Farnes Deep (NEFD)

3.1.1 Monitoring Objectives 1-3

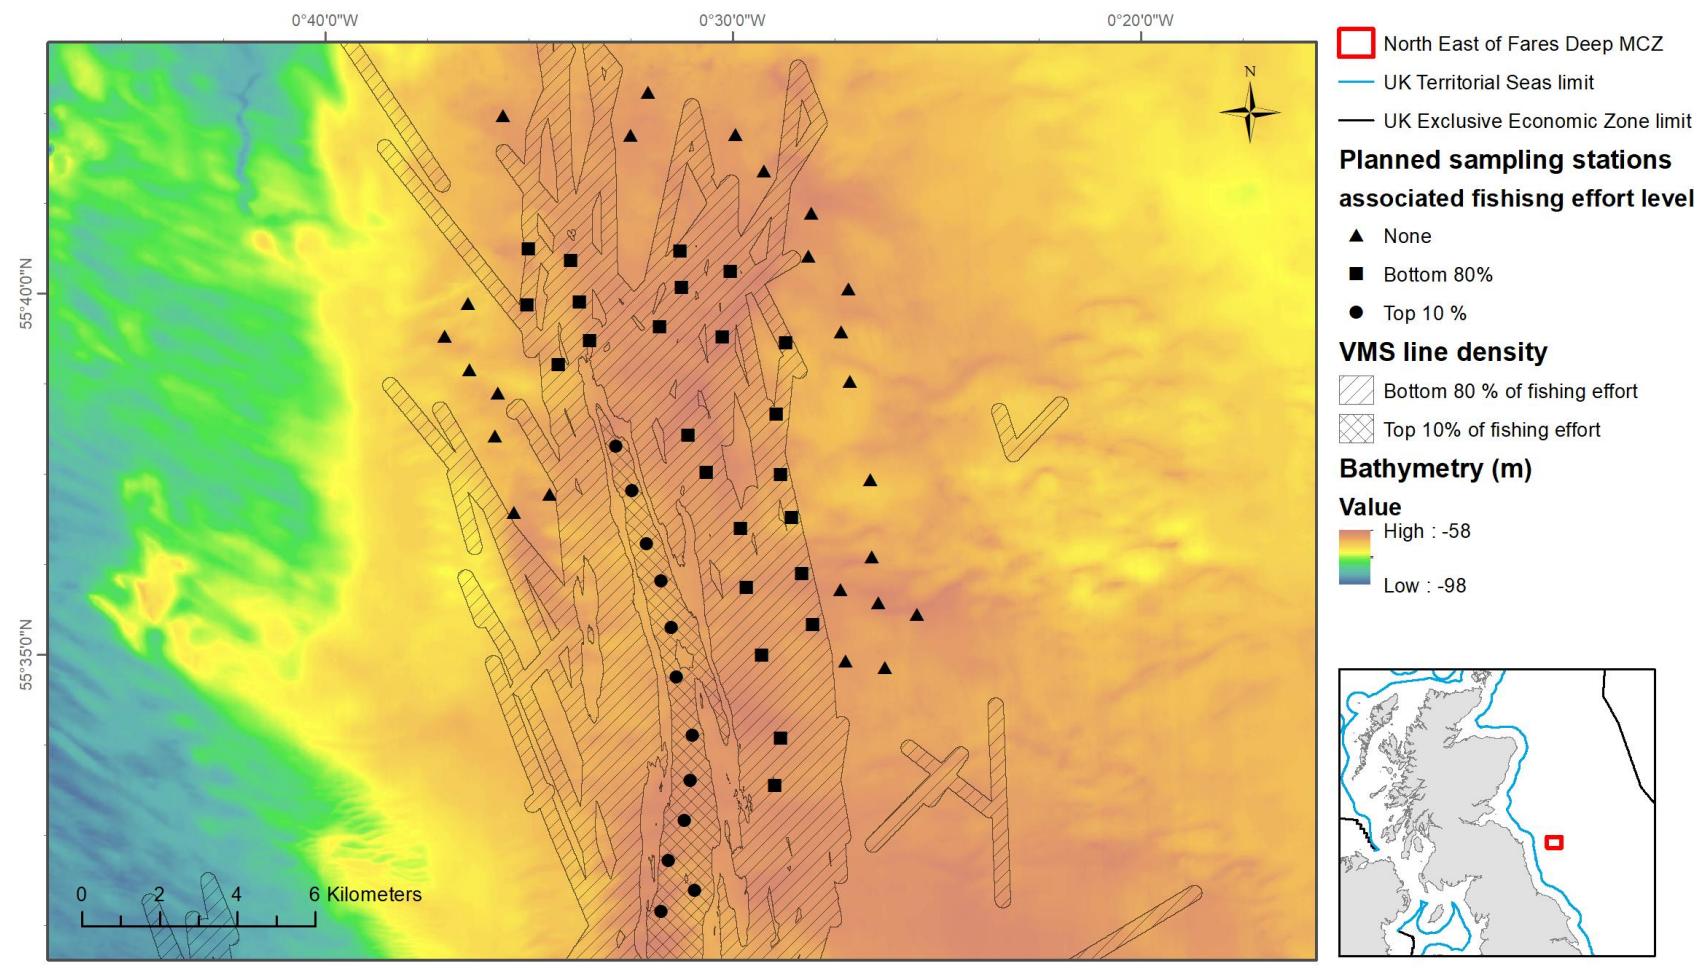

For NEFD MCZ site an area of interest containing the south-east corner of the MCZ plus the area immediately outside the MCZ was selected. This area was chosen as the south-east corner of NEFD MCZ overlaps with the area used by a sand eel fishery. An updated basic EUNIS habitat map for the larger area around the MCZ was produced using CHP bathymetry and backscatter with ground truth samples collected on previous surveys of the MCZ (CEND0412 and CEND1016). The map indicates the area of interest and the adjacent area outside the MCZ consist of a mosaic of 'A5.1 Sublittoral coarse sediment', 'A5.2 Sublittoral sand' and '5.4 Sublittoral mixed sediments' (Figure 3). As the map is based on old CHP data, it cannot be considered entirely accurate for current conditions. The delineation of 'coarse' vs. 'mixed' substrata is particularly uncertain. None of the areas identified as 'A5.4 Sublittoral mixed sediments' are subject to the higher level of fishing pressure. As a result, the study is concentrated on the areas mapped as 'A5.1 Sublittoral coarse sediment' and 'A5.2 Sublittoral sand' BSH. It is, however, likely that some of the samples will contain 'A5.4 Sublittoral mixed sediments'.

60 x 0.1m² Hamon Grab stations were identified; these were stratified across two BSH (coarse and sand), as well as three levels of fishing effort (none, bottom 80% of fishing effort, top 10% of fishing effort (Figure 3). Fishing effort was calculated based on UK and non-UK vessel monitoring system (VMS) pings from 2014 – 2016 and was associated with the shallower areas of the study site (Figure 4). At each station five replicate grab samples were collected within a 50m radius bullring, with the vessel moving approximately 10m between each replicate. The 0.1m² mini Hamon Grab (section 0) was used at this site for collecting particle size analysis (PSA) and macrofauna samples. Cobbles and/or the species FOCI *Arctica islandica* were measured (length, width, and depth) and weighed, when collected in a grab sample (Figure 5). The cobbles and damaged *A. islandica* specimens were included in the macrofauna samples. Intact *A. islandica* were returned to the seabed; these data will be included in the final analysis. This sampling strategy was primarily designed to address objectives 1 and 2 however any samples containing *A. islandica* contributed to objective 3 (Table 3).

3.2 Farnes East

3.2.1 Type 1 Monitoring of Mud BSH and ‘Sea pens and burrowing megafauna’ (FRNE objective 1)

The existing data of FRNE MCZ do not allow for adequate characterisation of the ‘Subtidal mud’ BSH and ‘Sea pens and burrowing megafauna’ habitat FOCI features at the site, or an estimation of sufficient stations to detect recovery of the habitats. Consequently, the survey objective for the mud habitats was to characterise the ‘Subtidal mud’ BSH and the ‘Sea pens and burrowing megafauna’ habitat FOCI (Table 4 – objective 1). The sampling was designed to obtain observations on the presence and abundance of epifaunal and infaunal taxa, including sea pens, as well as burrows as indicators of burrowing megafauna. The sampling design aimed to provide the necessary data to both establish the current extent of the ‘Sea pens and burrowing megafauna’ habitat FOCI and inform future monitoring surveys.

The criteria outlined by JNCC (2014) state that the Sea pens and burrowing megafauna habitat FOCI should be defined through multiple sightings of burrows and/or mounds attributable to relevant species across either a video tow, or in a sufficient number of still images, to identify the burrows and/or burrowing species as at least “frequent” on the SACFOR scale.

Data ideally required to confirm this habitat type include:

- (1) video and stills imagery to confirm burrows and/or mounds and, where present, sea pens;
- (2) infaunal grab samples to confirm relevant fauna (although see above); and
- (3) PSA data to confirm a fine mud habitat (JNCC 2014).

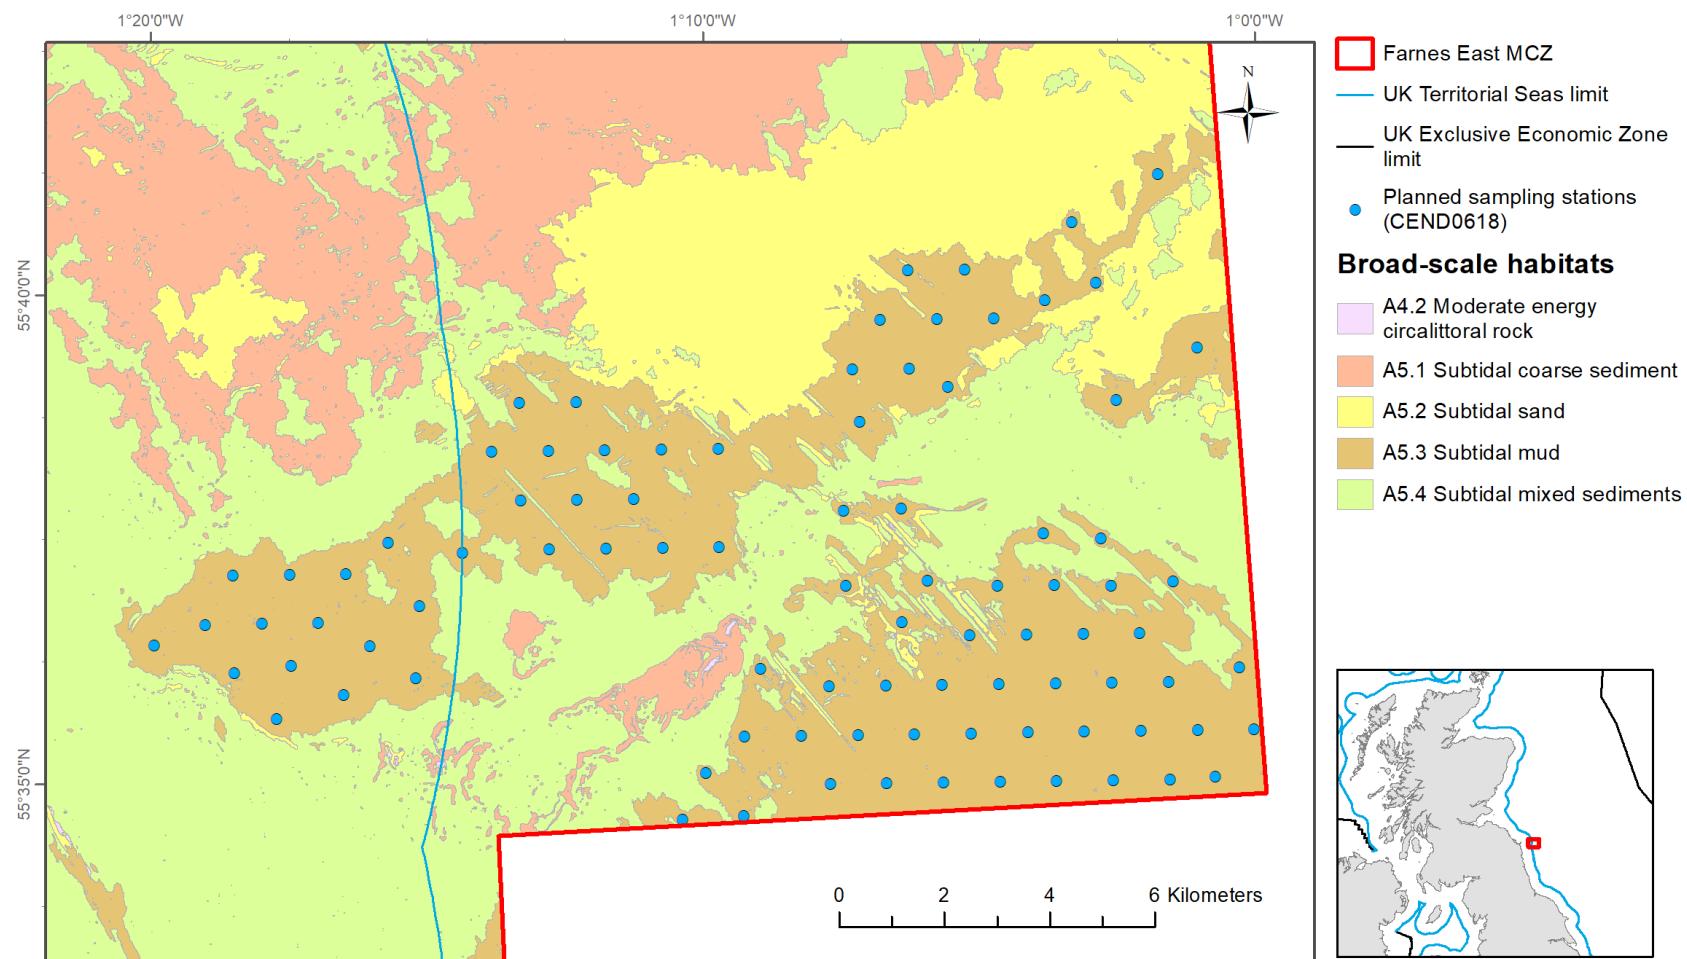

The mud feature at Farnes East consists of two large basins and additional smaller patches of mud (Figure 6). Existing data suggest the two largest basins differ in their particle size distribution; in that the southern basin has a higher mud content, whilst the northern basin is sandier. The southern basin is also currently fished.

A power analysis of grab samples collected in 2014 and assigned as mud BSH suggested 45 stations are needed to detect a 20 percent decrease in the number of individuals recorded from the mud BSH (Power = 0.8, p = 0.05).

90 planned survey stations were located in the two main mud basins, 45 stations each. An equidistant triangular grid was used with planned stations a minimum of 1km apart. Each station included:

- a 100m camera sledge tow (see section 4.3 for details about the camera sledge), and
- a single 0.1m² Hamon Grab (see section 4.2 for details about the Hamon grab) sample

The location of the planned stations can be seen in Figure 6. A subset of these stations (n = 4) also formed part of the sampling design for Objective 2.

© Crown Copyright 2019. Contains JNCC/Cefas information licenced under Open Government Licence V0.3. Coastline: GSHHG v2.3.6. Administrative boundaries: UKHO licenced under Open Government Licence V0.3. Map and inset projection; WGS84 UTM 30 N

Figure 6. Two areas of A5.3 Subtidal mud showing the distribution of planned sampling effort in the northern and southern mud basins of Farnes East MCZ. N.B. a subset of these stations ($n = 4$) formed part of objective 2. BSH data source Murray *et al.* (2015).

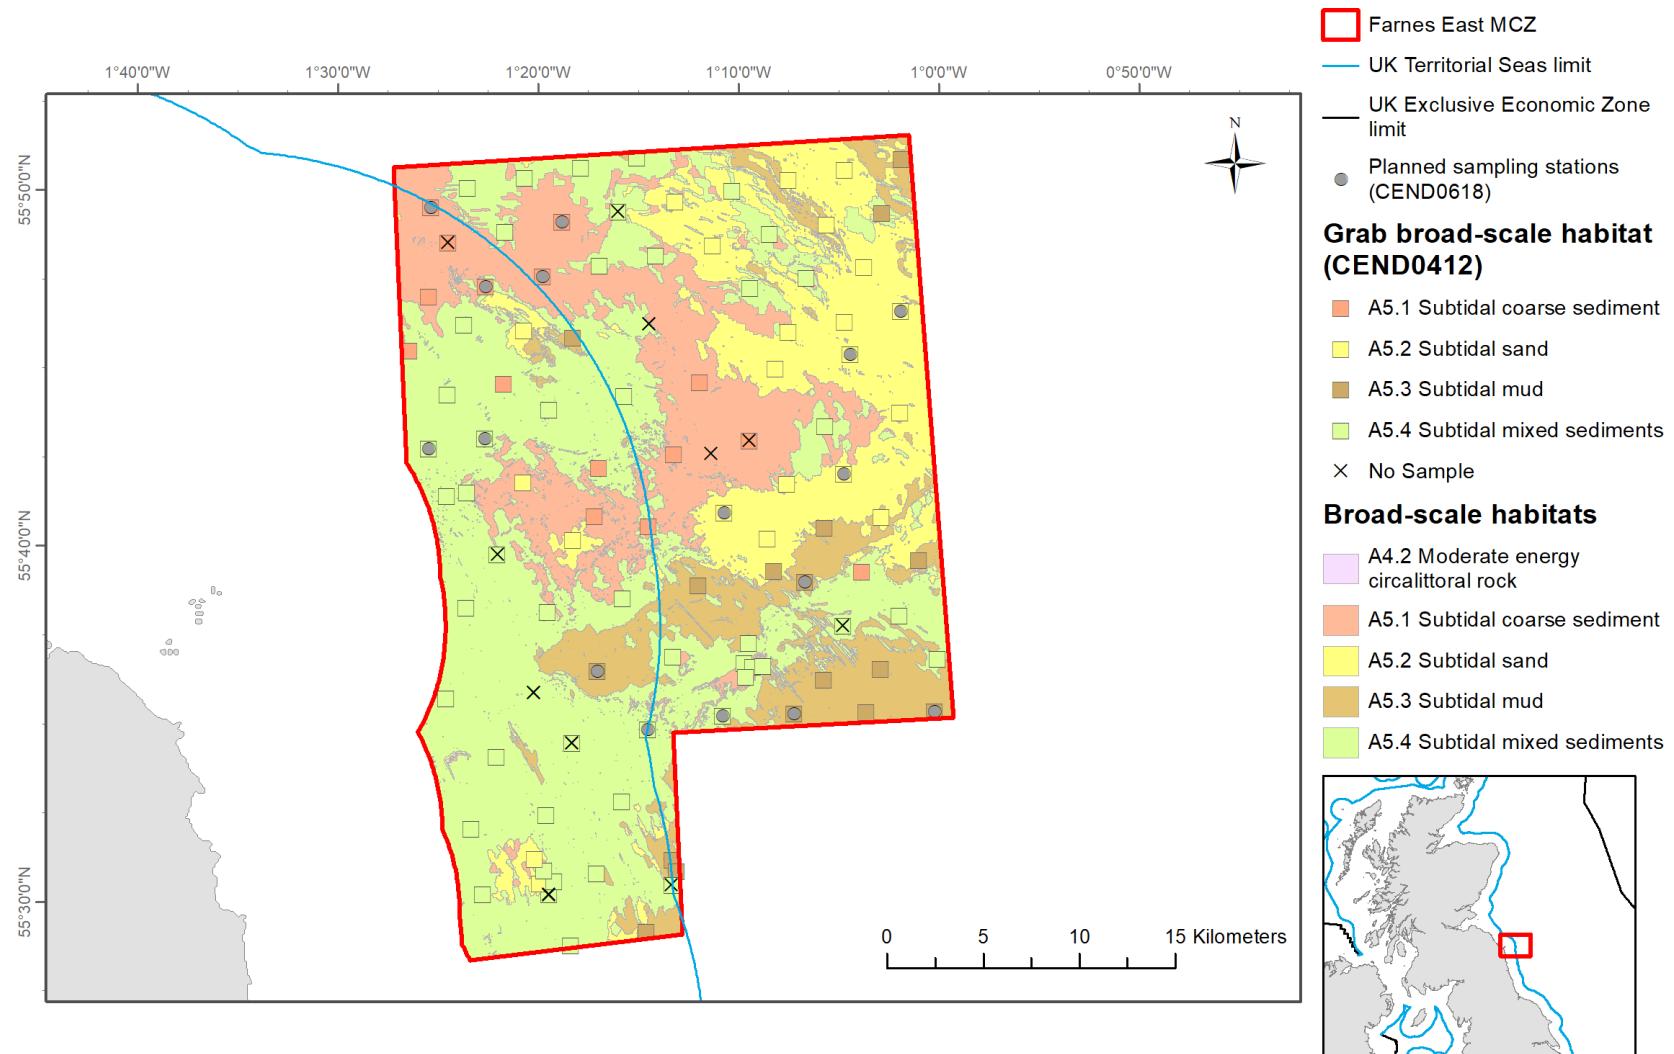

3.2.2 Type 1 Monitoring of all sedimentary BSH (FRNE Objective 2)

There are four sedimentary BSH present at FRNE – ‘A5.2 Subtidal coarse sediment’, ‘A5.3 Subtidal sand’, ‘A5.4 Subtidal mud’ and ‘A5.5 Subtidal mixed sediments’ (Figure 7). Particle size analysis (PSA) of existing grab samples, and power analysis using species richness and abundance metrics from faunal data (Appendix 1) both indicate that all the BSH have very high in-group variability. Variability within each BSH class is too great to consider them uniform units for sampling using a random sampling approach. To capture the whole gradient of particle size distributions across the site, whilst at the same time reducing variability in sampling units used for future comparison, it was decided to sample a smaller number of increased replication monitoring stations across a range of particle size distributions within each BSH. Monitoring single stations, instead of BSH classes, was chosen to reduce variability among samples and increase the power to detect temporal change within stations. Including multiple stations per BSH will give confidence over ‘representativeness’ of stations of the whole habitat type. Replication will quantify within-station variability and allow for robust time-series trend analysis for monitoring.

Increased replication monitoring stations were selected at FRNE based on the stations sampled on CEND0412 (Figure 7). Using previously sampled stations as monitoring stations provided the best chance of sampling the range of conditions at the site. Each station was expected to be more uniform between replicates than between stations. It must however be noted that, although the replication at stations will address the fine-scale spatial variability potentially present at stations, temporal variability can only be assessed and accounted for after multiple sampling events. BSH assigned to each station following sample analysis will be invaluable in terms of reporting and analyses, and for developing future monitoring survey plans.

Each of the four BSH were divided into two subtypes (See Appendix 5 for more detail) and two sampling stations were located in each subtype, giving a total of 16 stations (4 BSH x 2 subtypes x 2 stations = 16 stations) (Figure 7). 10 replicate grabs and a single drop camera transect were planned for each station (Figure 8). These samples address FRNE objective 2 (Table 4).

Infaunal community analysis of CEND0412 data was used to verify that the planned stations also captured the variation present in the infaunal macroinvertebrate community at Farnes East MCZ (See Appendix 5 for more detail).

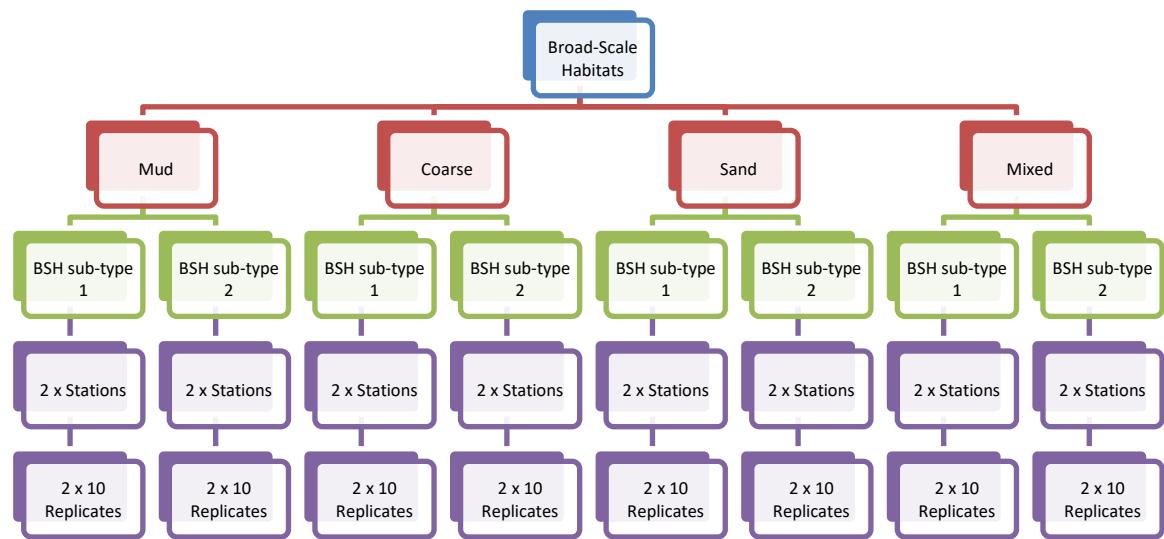

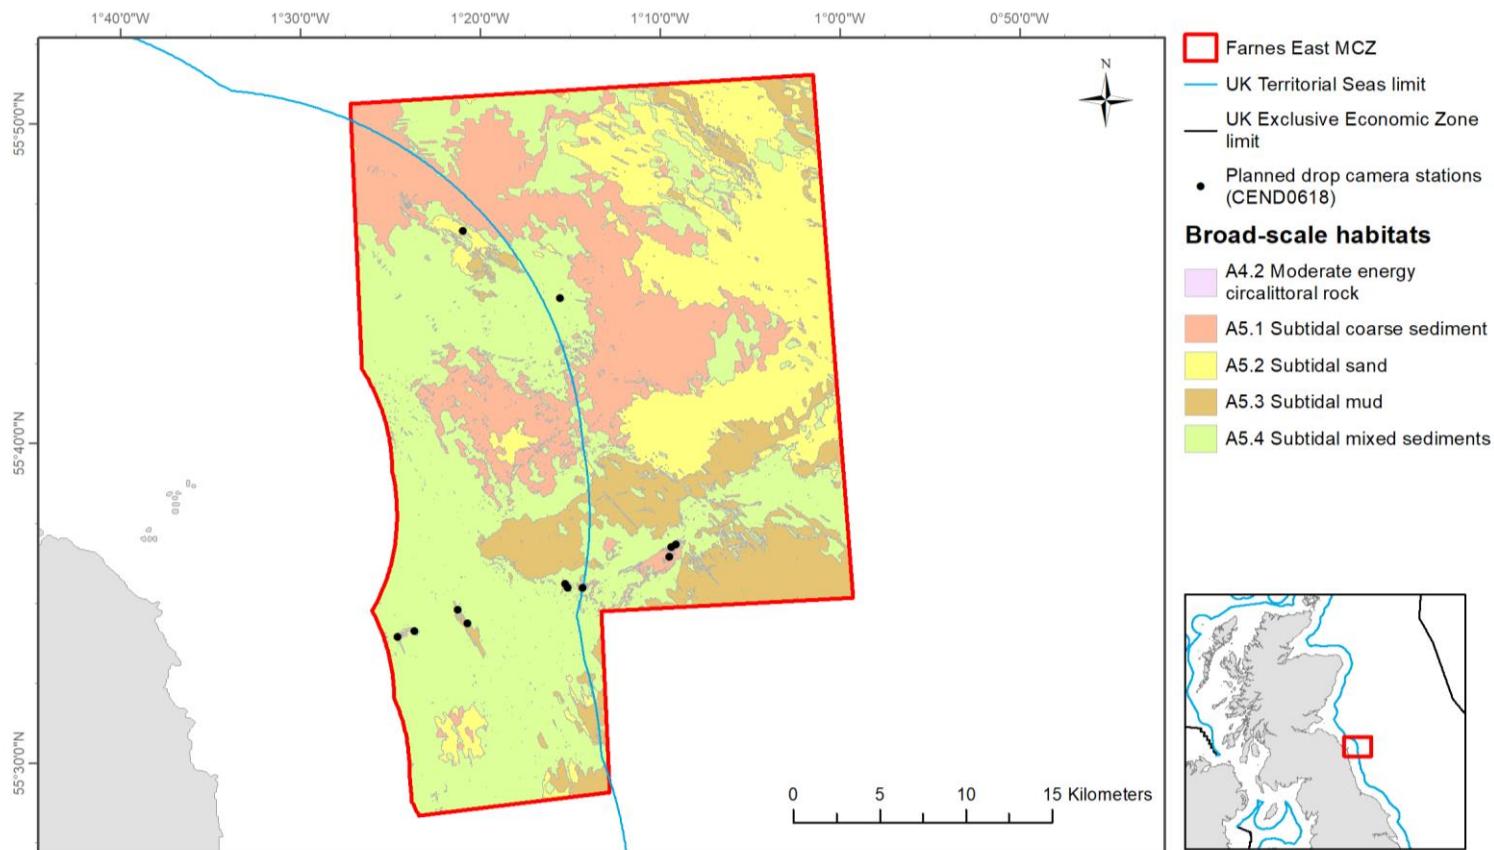

Figure 8. Survey design for BSH grab survey. Four BSH, each containing 2 BSH sub-types. Each sub-type contains 2 stations, each with 10 replicate grabs.

3.2.3 Type 1 Monitoring of Moderate energy circalittoral rock (FRNE Objective 3)

A third objective was planned to monitor small outcrops of moderate energy circalittoral rock that occur at the site (Table 4 – objective 3). The habitat map was used to identify 12 locations where the rock outcrop was large enough to conduct a 120m video transect using the drop camera (Figure 9). The objective of the drop camera survey was to establish a taxon list for future comparison.

Figure 9. Planned locations of drop camera tows over Moderate energy circalittoral rock at FRNE MCZ. BSH data source Murray *et al.* (2015).

3.2.4 Type 1 monitoring of the supporting processes relating to designated BSH types (FRNE objective 4)

The Ecosystem Monitoring Version 2 (ESM2) logger was mounted to the camera frame (drop frame or sledge) and recorded data during each camera transect. Therefore, all camera work carried out under FRNE objectives 1-3 (Table 4) contributed to this objective. Water samples from the ships ferry box were used to calibrate the data. More information on the ESM2 logger and the ferry box can be found in sections 4.4 and 4.5 respectively.

3.2.5 Type 1 monitoring of the quality and quantity of habitat supporting species FOCI Ocean quahog (FRNE objective 5)

Ocean quahog collected using the 0.1m² Hamon grab at FRNE are recorded following the same procedure described in section 3.1.1. A subsample for PSA will also be retained from these stations.

Additionally, Ocean quahog siphons may be visible in video and still images collected from planned camera transects at FRNE. Samples planned to fulfil FRNE objective 1 and to a lesser extent FRNE objective 2 (as objective 2 is unlikely to encounter suitable habitat for Ocean quahog), will contribute to FRNE objective 5 (Table 4).

4 Sampling methods

The survey of the two sites was undertaken aboard the RV *Cefas Endeavour*. Details of the vessel and the equipment used are provided in Appendix 2. The survey operations and protocols are described below.

4.1 Survey Project Team

The survey team for the duration of the fieldwork included Cefas and Joint Nature Conservation Committee (JNCC) marine scientists. 24-hour operations were conducted throughout.

Deck Scientist	

4.2 Sediment and macrofauna samples

The grab system employed for the study comprised a 0.1m² mini Hamon grab (Figure 10). Samples were collected from the planned ground-truth stations anywhere within a 50m

radius bullring centred on the station location. On recovery, the grab was emptied into a large plastic bin and a representative integrated sub-sample of sediment (approximately 0.5l) taken for Particle Size Analysis (PSA). The PSA sample was stored in a labelled plastic container and frozen ready for transfer to a laboratory for analysis. The remaining sample was photographed, and the volume of sediment measured and recorded. Benthic fauna was collected by washing the sample with sea-water over a 1mm sieve. The retained >1mm fraction was transferred to a labelled container and preserved in buffered 4 % formaldehyde for later analysis. A visual assessment was made of the sediment type sampled by the grab and noted on the field records, assigning the sample to a preliminary Folk class and its equivalent BSH.

Figure 10. 0.1m² mini Hamon grab similar to that used on CEND0618.

4.3 Seabed imagery

Seabed imagery was acquired for later assessment of the benthic epifaunal community present using a camera sledge (Figure 11). A drop camera system was also taken for areas where the seabed surface proved too coarse to safely deploy a camera sledge. In practice the drop camera system was not required as only monitoring objectives requiring the camera sledge were addressed (Table 4). High definition video footage and digital still images were captured during 11-minute tows. Fan lasers were mounted on the camera sledge frame. These provide a fixed known distance allowing quantification of sampling (Figure 12). Sensors logging bottom temperature, altitude, bearing and depth recorded data for the duration of the tow.

Figure 11. Camera sledge system used on CEND0618.

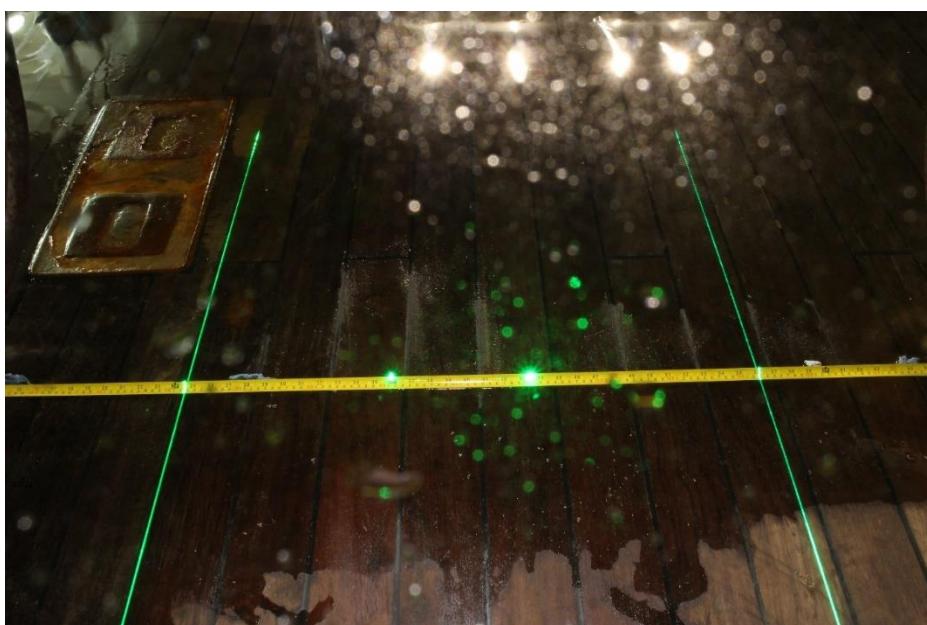

Figure 12. Fan (80cm separation) and spot lasers (19cm separation) on the camera sledge being measured prior to deployment.

4.4 Physical environmental parameters

An ESM2 logger was attached to the camera frame to record a suite of environmental variables across the horizontal profile of each video tow. The ESM2 logger was fitted with a conductivity / temperature (CT) sensor, chlorophyll fluorometer, oxygen optode and two optical backscatter sensors to gather salinity, chlorophyll, dissolved oxygen and turbidity data.

The RV *Cefas Endeavour*'s 'ferrybox' is an underway continuous logging system and was operated throughout CEND0618. This instrument measures the surface values of the same parameters recorded using the ESM2 logger, with an additional sensor measuring variable

fluorescence (a measure of phytoplankton photosynthetic efficiency). These data will provide high quality physical parameters to relate to various benthic observations and contribute to achieving FRNE objective 4.1 (Table 4). These data will also be used to supplement Cefas' shelf sea modelling activities.

4.5 Water sample processing

As with most, if not all, *in-situ* instrumentation, data need to be validated and the equipment calibrated to ensure robust datasets. Discrete water samples were collected using the continuous flow 'ferrybox' system for salinity. Salinity samples were collected by syphoning off water into rinsed clean glass salinity bottles. The lip and opening of the bottle were wiped clean to prevent salt formation and potential loss of determinant. An insert is placed in the neck of the bottle to prevent evaporation and the bottle is then capped, itemised and logged. It's important that the *in-situ* samples are taken from the same water mass the instruments are measuring. The camera sledge frame (with the attached ESM2 logger and sensor array) was held at 4m below sea level for a few minutes while taking the water sample from the 'ferrybox'. The ship's thrusters are not in use during this process as they are known to mix and ventilate the surface waters significantly.

5 Survey Narrative

The survey equipment and consumables were mobilised in advance of sailing. All times are GMT.

23 April 2018: A vessel induction was given at 11:00 for staff who had not received one in the last six months. The vessel left Lowestoft at 15:00 on the 23 April 2018 and transited to North East of Farnes Deep MCZ.

24 April 2018: The vessel arrived at the first station of NEFD at 09:00 24 April 2018 at which point a Hamon grab toolbox were held with all staff. Grab samples were collected continuously through the day.

25 April 2018: Hamon grab sampling continued throughout the day. A successful "wet test" deployment of the camera sledge system was carried out on at 15:00 in preparation for the Farnes East site.

26 – 27 April 2018: Hamon grab sampling carried on out for a further 48 hours without incident.

28 April 2018: Sediment sampling was continued at North East of Farnes Deep MCZ until completion at 05:38. The vessel left the site at 06:00 and arrived at Farnes East at 08:00. Hamon grab sampling began at 09:02. Two camera test deployments were carried out at 09:25 to allow for adjustments. Grabbing continued while these adjustments were made before camera sledge sampling began at 11:41. Simultaneous camera and grab sampling was carried out for the rest of the day.

29 April 2018: Camera sledge operations were stopped at 23:30 after a notable kink and damage appeared in the fibre optic cable (Figure 13). At the same time, there were two occasions when the camera sledge lights and lasers unexpectedly turned on, possibly because of the damaged cable. By this point 26 video transects had been successfully collected, however, very high levels of phytodetritus in the water column meant that the visibility was often poor. It was decided to focus on taking sediment samples at the Objective

2 sites (Type 1 Monitoring of all sedimentary BSH) while the camera issues were being investigated and resolved. Grab sampling continued throughout the day without incident.

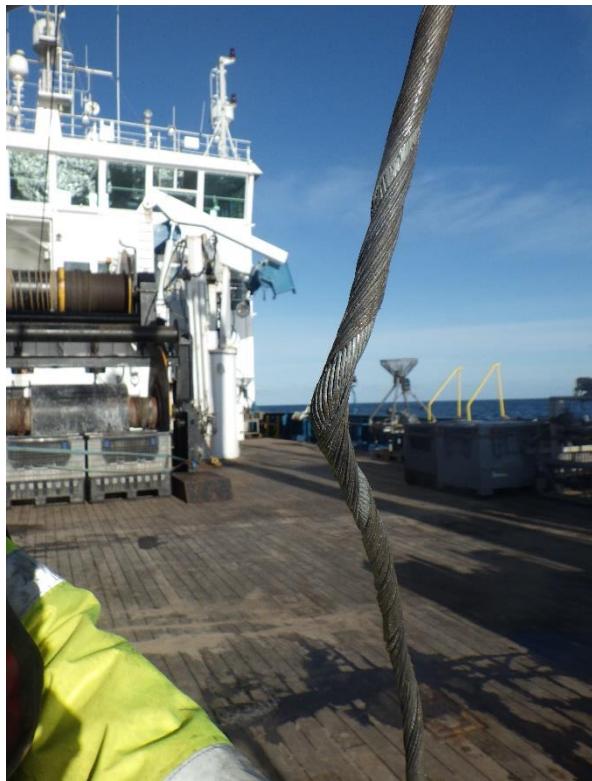

Figure 13. Damage to the camera sledge's fibre optic cable.

30 April 2018: Hamon grabbing operations continued for the next 24 hours with 68 further grab samples taken. The high intensity of operations took its toll on the Hamon grab, which had to be replaced after the welds on the grab arm pivot were ripped apart (Figure 14). This resulted in 30 minutes of downtime while the grab was swapped for a replacement.

Around this time, it was determined that the number of stations planned for the Farnes East MCZ site was overly optimistic and that despite the favourable conditions, several stations would have to be dropped due to lack of time. FRNE objective 3 (type 1 monitoring of moderate energy circalittoral rock) was dropped reducing the workload by 12 stations. FRNE objective 1 (type 1 monitoring of mud BSH and 'Sea pens and burrowing megafauna') was then revised from 90 stations to 50 stations. The revision meant 25 stations in the northern mud basin and 25 stations in the southern mud basin would be sampled. These were determined to still be enough to carry out a full assessment of the area of interest.

Figure 14. Damaged weld on the mini Hamon Grab.

1 May 2018: The damaged fibre optic cable was replaced with a coaxial cable. This did mean a decrease in image quality from full HD to 720P. To avoid a repeat of the lights and lasers incident, changes were made to the software settings and a revised risk assessment and standard operating procedure were developed. Camera sledge operations recommenced at 15:00 after staff carried out a toolbox talk to understand the changes and new procedures. Once again, the visibility on the video and still images poor due to high levels of phytodetritus in the water column. Hamon grab sampling continued throughout the day without incident.

2 May 2018: Simultaneous camera and grab sampling went on until 03:30. At this point the weather deteriorated and it was no longer possible to sample using the camera sledge. Grab sampling continued until 06:00 when the weather deteriorated further. All sampling was paused at 06:30 until conditions improved with camera sampling restarting at 08:00 and grab sampling at 15:35. Operations continued together until 17:30. At this point the bow thruster of the vessel developed an oil leak. Condensation also appeared on the inside of the camera housing. The camera was swapped for a replacement and the crew carried out preventative maintenance on the bow thruster. Simultaneous grab and video sampling resumed at 22:00.

3 May 2018: The grab and video operations continued until the last sample was collected at 13:52. The vessel left Farnes East MCZ at 14:00 and transited to Lowestoft Port.

4 May 2018: The *RV Cefas Endeavour* docked at 12:00. Sampling gear was demobilised, and samples transferred to storage in readiness for processing.

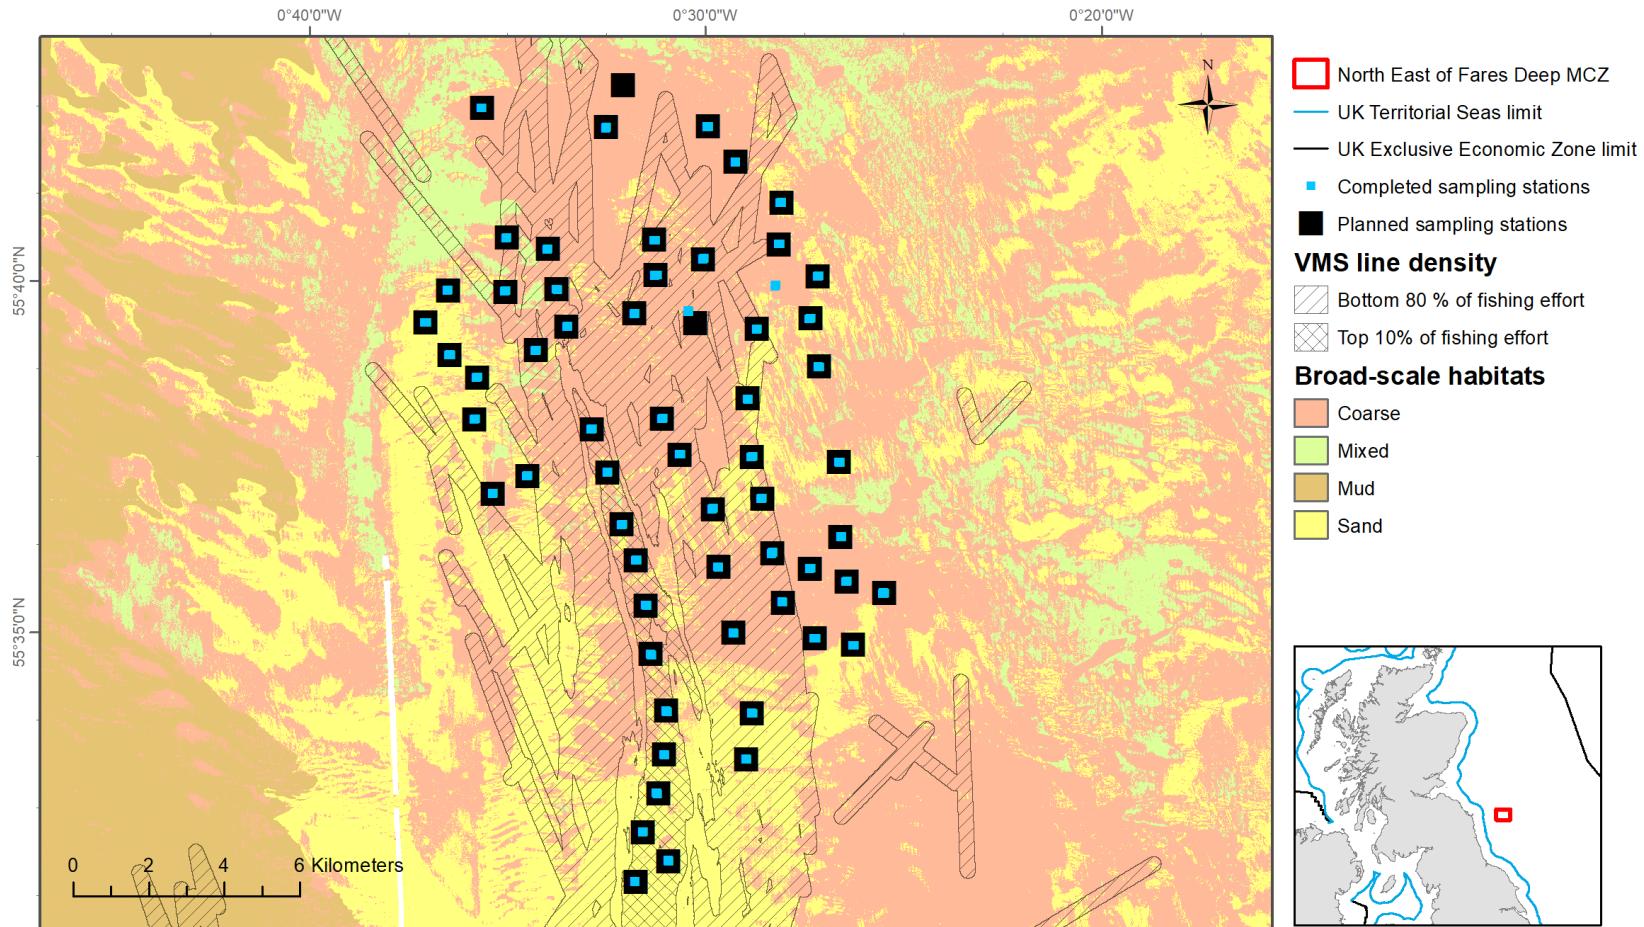

6 Environmental data acquisition

6.1 North East Farnes Deep MCZ

All sampling objectives for NEFD were completed on survey. Five replicate Hamon grab sediment samples were successfully collected from 58 of the original planned 60 stations. At station NEFDM001 samples were too small to be valid. At station NEFDM009 the sediment was too coarse and only yielded two samples. Two additional stations were added to achieve a total of 60 successfully sampled stations, each with five replicates (Table 6, Figure 15). The analysis of the samples will be completed and reported on in a later report. Metadata on the samples is given in Appendix 6.

Table 6. Summary of samples collected at North East Farnes Deep MCZ on CEND0618. *See Table 3 for full monitoring objectives.

Objective*	Sub-objectives	Sample type	Stations planned	Stations attempted	Successful stations	No. of samples	No. of replicates at each station
1. Collect evidence to inform Type 2 (operational) monitoring of the; • extent and distribution; and, • structure and functions, and quality and composition of the biological communities and typical species associated with subtidal coarse sediment, subtidal sand, features of NEFD and the surrounding area.	1.1 Acquire quantitative infaunal data using grab samples within areas of interest within and outside NEFD (this will fulfil criteria in sub-objectives 2.1 and 3.1)	PSA / Macrofauna	60	62	60	302	5
2. Collect evidence to inform Type 2 (operational) monitoring of the extent, distribution and physical structure of the subtidal coarse sediment, subtidal sand, subtidal mixed sediments and subtidal mud features of the NEFD.	2.1 Acquire sediment particle size data using grab samples within areas of interest within and outside NEFD (see sub-objective 1.1)	PSA / Macrofauna	60	62	60	302	5
3. Collect evidence to inform Type 2 (operational) monitoring of the quality and quantity of habitat supporting the species FOCI, Ocean quahog.	3.1 Acquire quantitative data using grab sampling and outside NEFD (Data collected in sub-objectives 1.1, where available, will be used to meet this objective).	PSA / Macrofauna	60	62	60	302	5

6.2 Farnes East MCZ

During the survey it became apparent that there was insufficient time to complete all objectives for Farnes East. This was partly due to the downtime with the camera sledge and partly an underestimation of the deployment time required for camera sledges (as opposed to drop cameras). FRNE objective 1 (type 1 monitoring of mud BSH and ‘Sea pens and burrowing megafauna’) was revised down from 90 stations to 50 stations. FRNE objectives 3, 2.3, and 2.4 were dropped altogether due to their lower priority (Table 4). The final number of stations and samples collected are given in Table 7. The locations of the stations sampled to achieve FRNE objective 1 and 2 can be seen in Figure 16 and Figure 17 respectively. Metadata for each sample is given in Appendix 6.

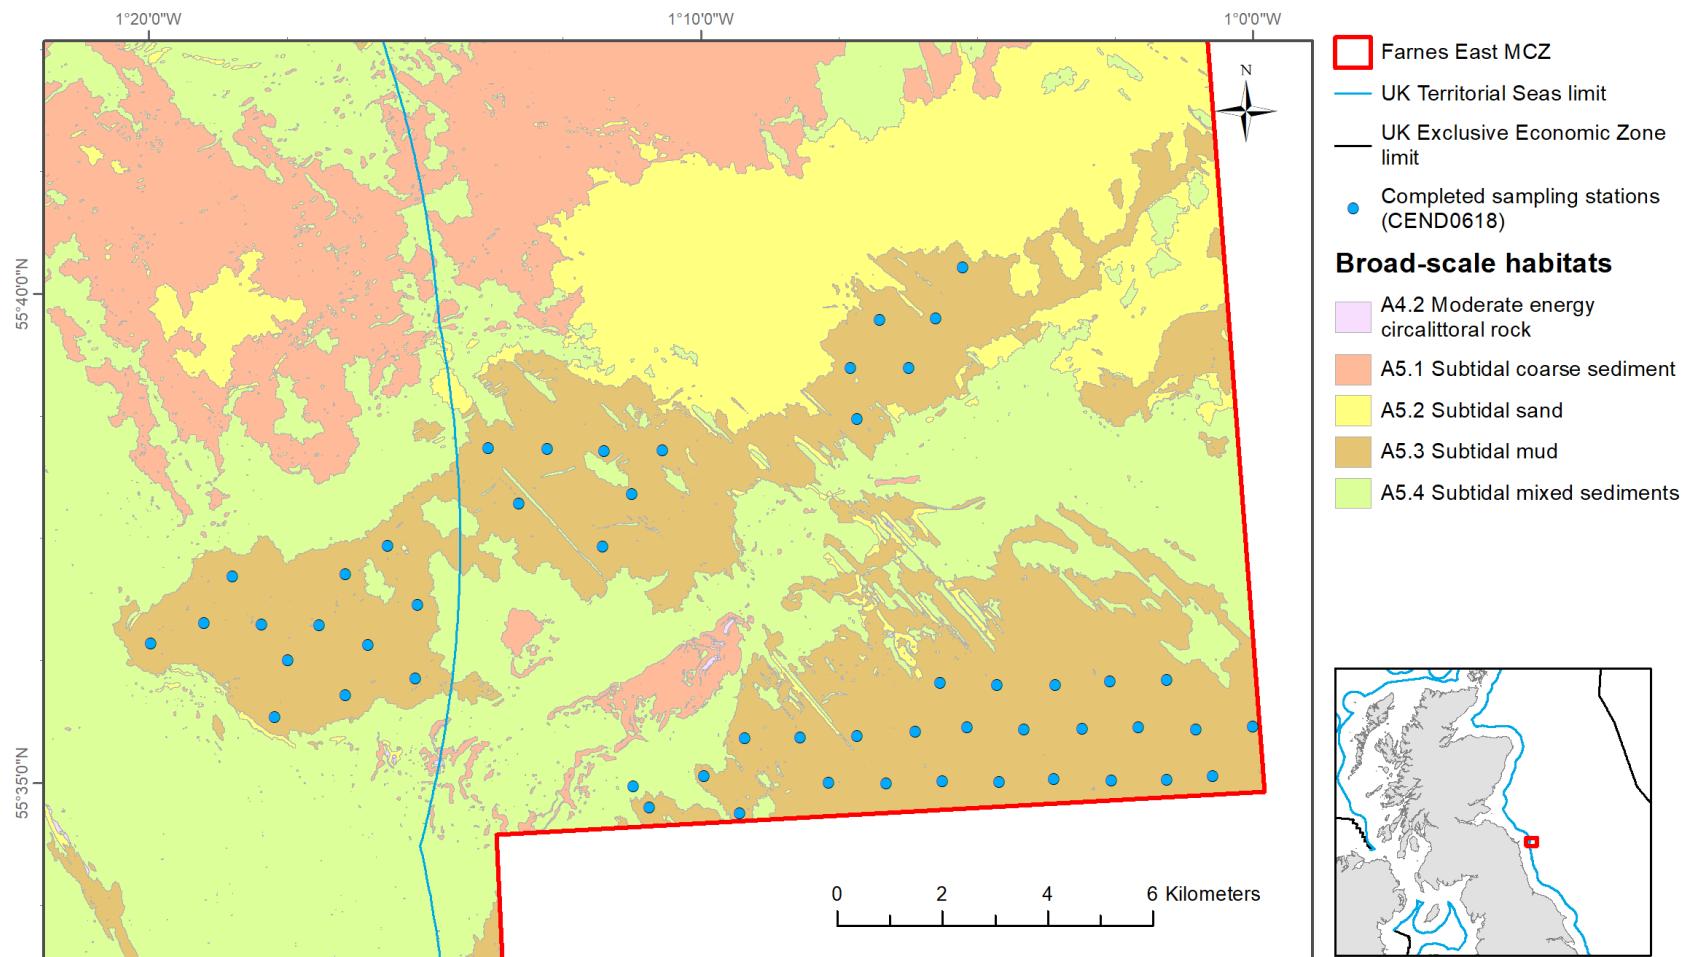

In order to calibrate data from the ESM2 logger, a total of 23 salinity samples were taken across the site and these contribute to achieving FRNE objective 4.2 (Table 4).

Table 7. Monitoring objectives for the Farnes East MCZ survey, including an indication of whether the objective was completed during CEND0618. *5 stations of objective 1 overlaps with 5 stations of objective 2. 127 camera samples were made at full HD. The remaining camera samples were at 720P after switching to the coaxial cable. ²ESM2 and Ferrybox data are examined separately post-survey and were not available at time of this report.

Objective	Sub-objectives	Sample type	Stations planned	Stations achieved	Replicates	Total no. of samples	Objective completed
1. Collect evidence to inform Type 1 (sentinel) monitoring of the biological and physical; • extent and distribution; and, • structure and functions, and quality and composition of the subtidal mud feature of FRNE and, where available, the quality and quantity of the habitat supporting the FOCI Sea pen and burrowing megafauna communities and, if available, the composition of the FOCI	1.1 Acquire quantitative infaunal data using a mini-Hamon grab (integrated with sub-objective 1.3). Camera sledge

The camera sledge was equipped with the following camera and specifications:

- Telemetry Operation over fibre optic cable
- 1080p high definition video camera
- 720p forward facing video camera
- 18 mega pixels underwater digital stills camera
- High power camera flash
- 20W high intensity led lights x 6 (2 forward facing)
- Dual scaling subsea lasers x 2 (spaced at 250mm)
- 250khz precision altimeter
- Combined compass & depth
- Temperature sensor
- Ultra-short base length positioning beacon

Positioning Software and Offsets

Vessel offsets are defined from the pitch roll centre of the vessel i.e. the Central Reference Point (CRP) is used by the Tower CEMAP software to calculate offsets to deployment gantry.

GPS fixes were recorded using the Tower Navigation system on RV *Cefas Endeavour*. This records the positional coordinates of the gantry from which the sampling equipment is being deployed, automatically compensating for the offset between these gantries and the GPS antenna, as well as the corrected position provided by the Ultra-Short Base Length HiPAP beacon, when in use.

The vessel offsets used to calculate a more accurate position for equipment deployed from the RV *Cefas Endeavour* are shown for the stern gantry, side gantry, and HiPAP (Figures 5 - 7).

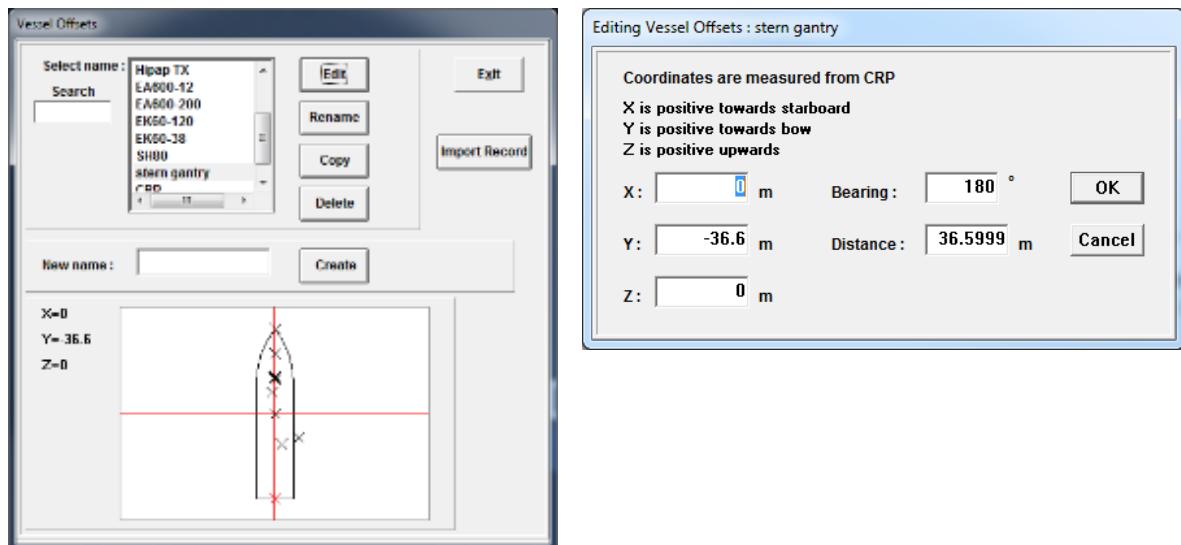

Figure 18. Stern Gantry vessel offsets in the Tower Navigation system.

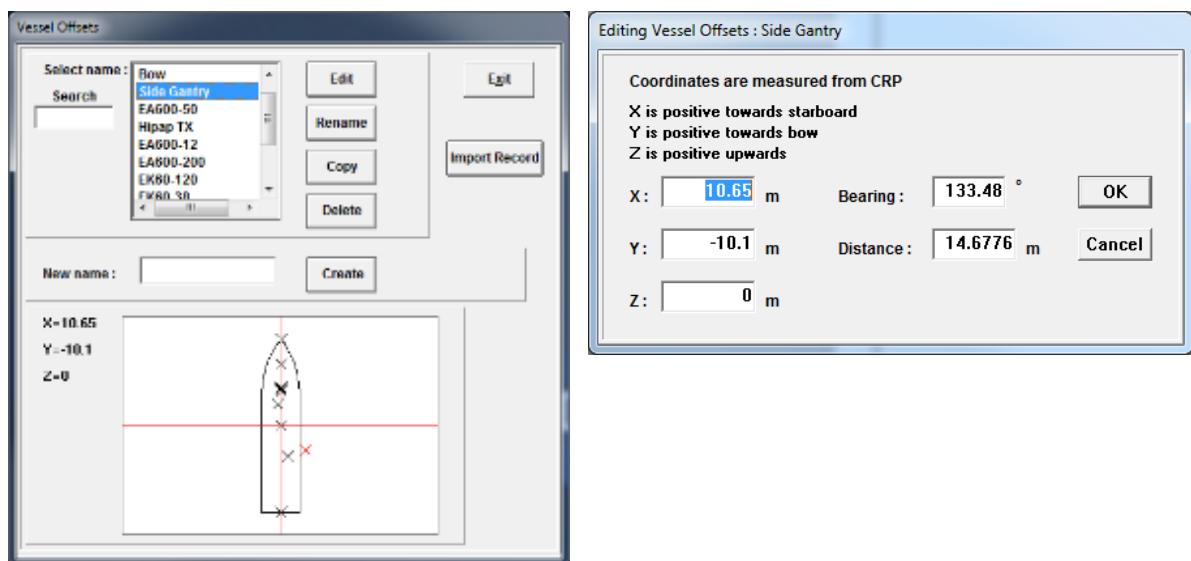

Figure 19. Side Gantry vessel offsets in the Tower Navigation system.

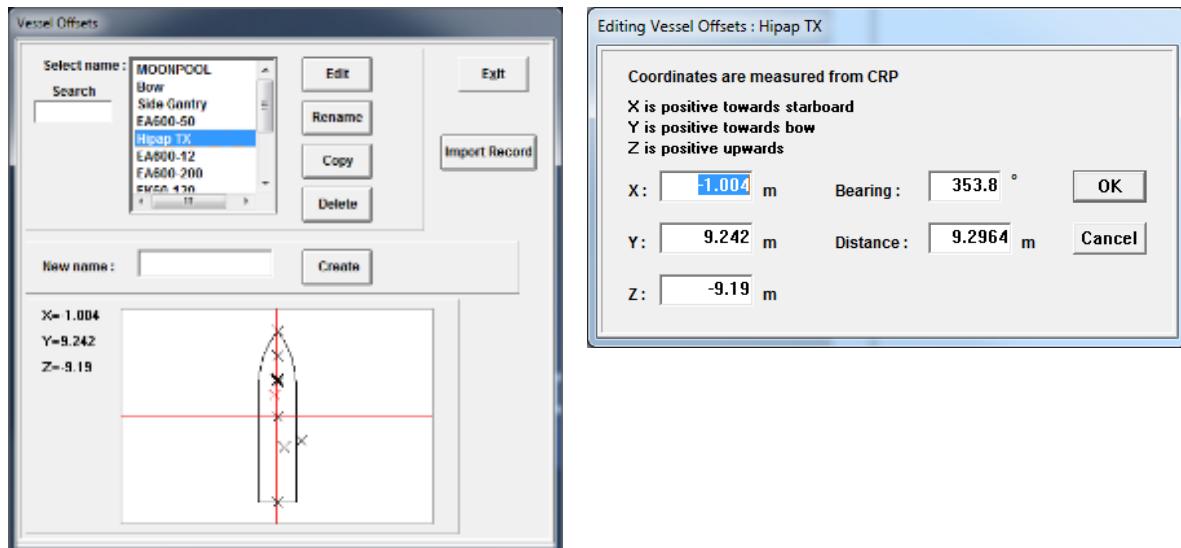

Figure 20. Hipap vessel offsets in the Tower Navigation system.

Appendix 5. Farnes East MCZ, BSH subtypes and infaunal community representation

Broad-Scale Habitat (BSH) subtypes

BSH subtypes were identified using summary statistics of the gravel, sand and mud fractions (Figure 21). The 25th, 50th and 85th percentiles of percentages of gravel, sand and mud were calculated for each BSH.

For coarse and mixed sediments, two subtypes (coarser and finer) were identified using the 25th and 85th percentiles of gravel and sand, whilst keeping mud at the median value.

For sand and mud, subtypes (muddier and sandier) were identified using the 25th and 85th percentiles of mud and sand, whilst keeping gravel at the median value (Figure 21).

This results in each BSH having two subtypes based on particle size distribution.

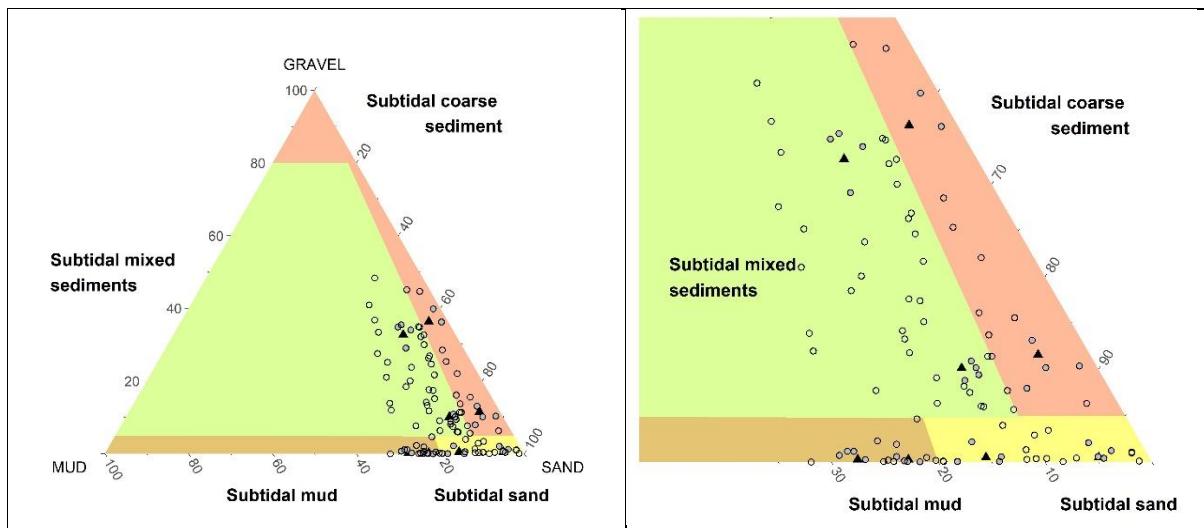

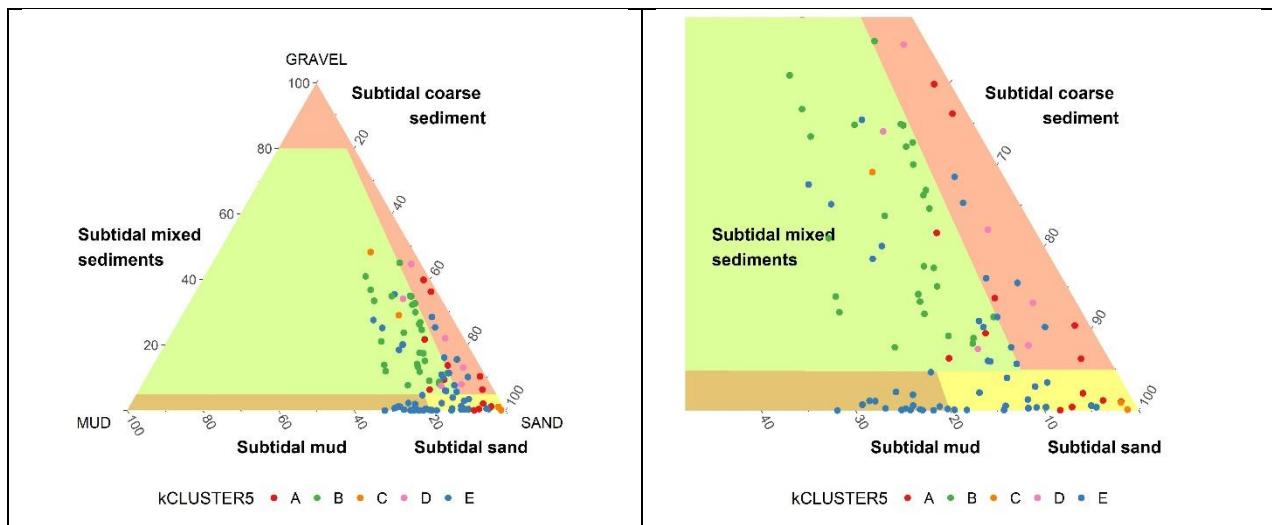

Figure 21. Folk triangle (left) and detailed view (right) showing the particle size distribution in grab samples collected at Farnes East MCZ from survey CEND0412 with centroids for two sub-regions (black triangles) in each BSH and the four stations nearest to each centroid (solid circles).

Representation of infaunal communities at FRNE

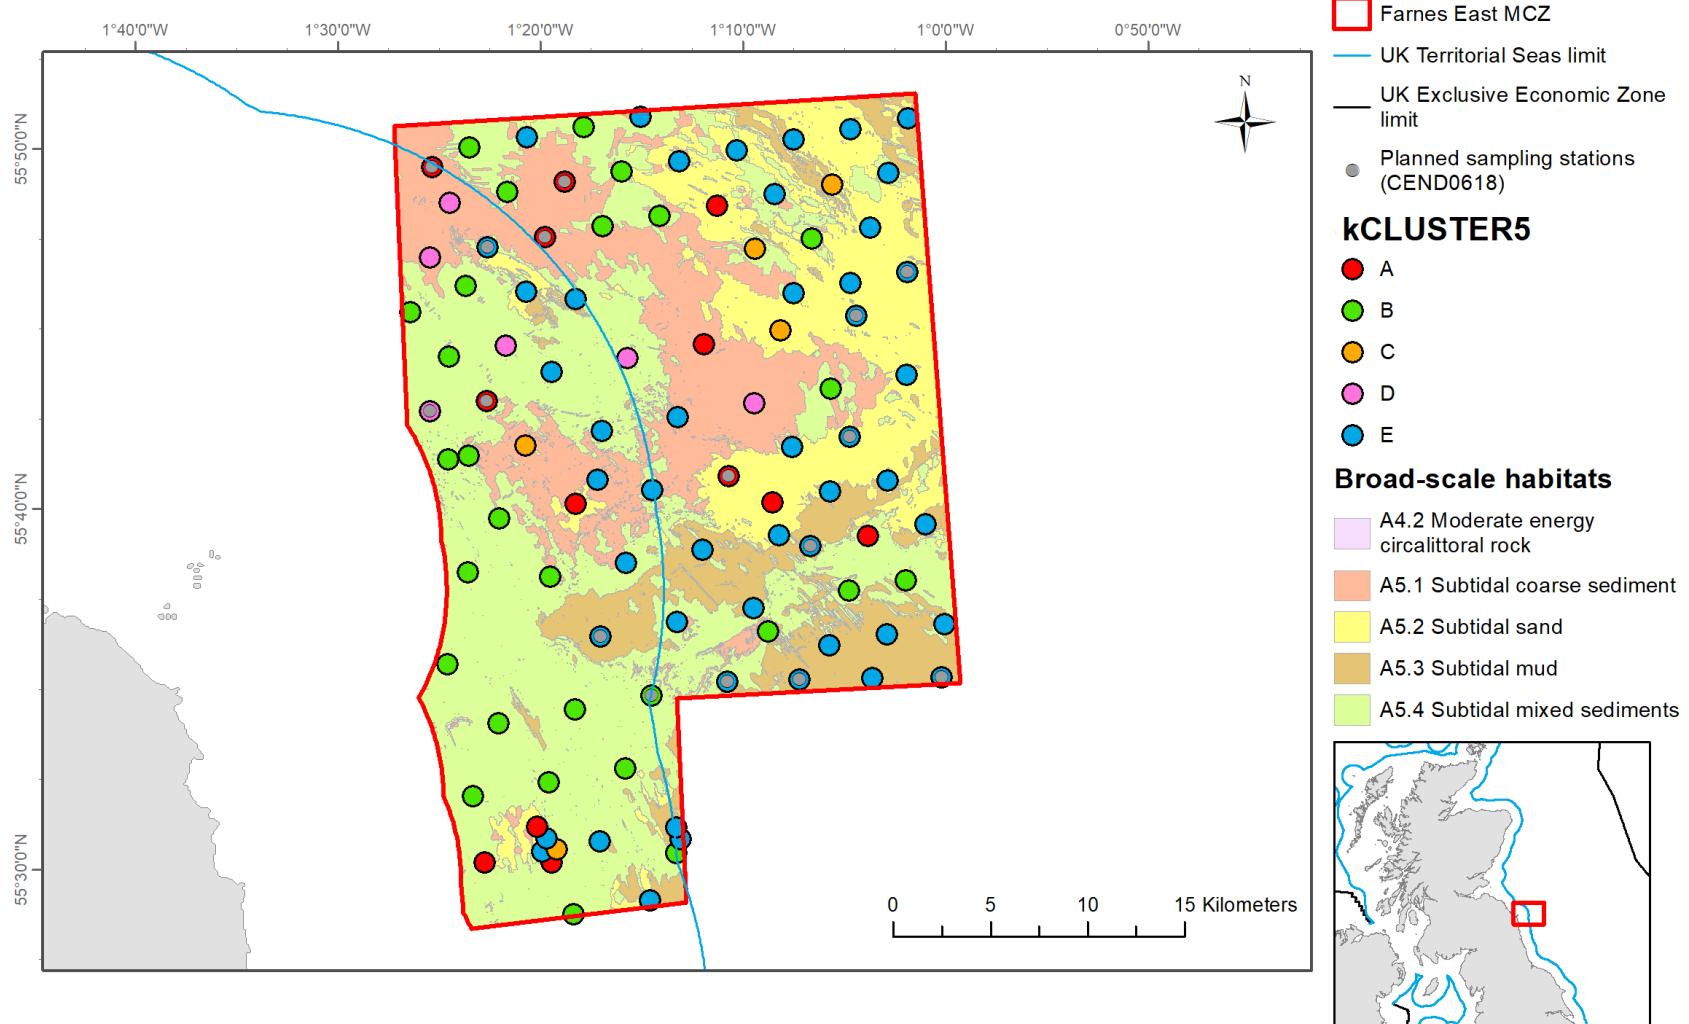

Infaunal community analysis was used to determine if the increased replication monitoring stations selected at FRNE also captured the variation present in the infaunal macroinvertebrate communities. CEND0412 Infauna data were checked for taxon revisions, truncated (colonials set to an abundance = one, vertebrate and pelagic taxa removed, etc.) and square root transformed. Cluster analysis was performed in Primer V7 using the kRCluster routine, setting the maximum number of groups to five. This faunal group allocation is presented in Table 10 and Figure 22 to show the variation in faunal assemblages within the mixed BSH, within the context of PSA distribution and geographically in Figure 23.

Table 10. Number of grab samples from CEND0412 allocated to each k-means cluster.

kCLUSTER5 group	Total number of sediment samples allocated to this group
A	13
B	28
C	5
D	6
E	48

**Figure 22.** Folk triangle (left) and detailed view (right) showing the particle size distribution in grab samples collected at Farnes East MCZ on CEND0412 with their associated infaunal group (kRCuster).

The four closest stations to the subgroup centroids were selected as potential sentinel stations and plotted in GIS (Figure 23).

Figure 23. The distribution of infaunal groups across the Farnes East survey site. BSH data source Murray *et al.* (2015).

Appendix 6. Survey metadata

Table 11. Hamon grab station metadata for North East of Farnes Deep (NEFD) and Farnes East (FRNE). Station Number is a sequential event number for the survey and thus changes each time a new gear is used, or a new location is sampled. Station Code is used to identify the location of the sampling station. Replicate = number of replicates in form A, B, C etc. the number indicates the number of attempts e.g. A2 = first replicate, second attempt. All positions are provided in decimal degrees, Latitude / Longitude WGS84.

Table 12. Camera sledge station metadata for North East of Farns Deep (NEFD) and Farnes East (FRNE). Station Number is a sequential event number for the survey and thus changes each time a new gear is used, or a new location is sampled. Station Code is used to identify the location of the sampling station. Replicate = number of replicates in form A, B, C etc. the number indicates the number of attempts e.g. A2 = first replicate, second attempt. All positions are provided in decimal degrees, Latitude / Longitude WGS84.
